My country is Greece. The population is about 10.37 million people. About 81% of the population lives in urban areas, while 19% lives in rural areas. Around 7% of the population is currently food insecure. Greece has a unitary parliamentary republic form of government. About 41% to 44% of the land is currently cultivated for agriculture. The major exports that are grown and harvested include olives, cotton, grapes, and refined petroleum products. The average farm size is about 12 to 17 acres, which is roughly the size of 12 to 17 football fields. Greece also has a Mediterranean climate, which means it often has hot, dry summers and cool, wet winters. This type of climate works well for growing crops like olives and grapes.

The average family size in Greece is about two to three people. Common jobs include working in healthcare, tourism, and technical support fields. The average yearly wage is around $33,000. A typical family's diet includes whole grains, seasonal vegetables, and large amounts of olive oil and fish, which are part of the well-known Mediterranean diet. Families usually buy their food from local markets or farmers markets, and they often cook with fresh, seasonal ingredients. Most schools in Greece are affordable and accessible, but healthcare can be more difficult to access depending on cost and availability. Nearly 100% of families have access to electricity, and most also have access to clean water, toilets, and telephones. Religion is also an important

part of daily life in Greece, with about 81% to 98% of people identifying as Greek Orthodox Christian.

The problem I am researching in Greece is the decline in the fishing industry. Fishing plays a major role in Greece's economy, especially in coastal and island communities, so this issue is affecting many people. The decline in fishing is caused by several factors. One major factor is a fleet reduction policy, which has reduced the number of local fishing boats allowed to operate. Because of this, fewer people are able to work in fishing, even though there is still a demand for captains and fishermen. This has led to over 18,000 people losing their jobs. This problem mainly affects coastal and island communities where fishing is a primary source of income. The environment is also being impacted. Changes in fishing patterns can disrupt the balance of marine ecosystems, which can harm habitats and affect other species that depend on those fish.

Some possible solutions include creating more aquaculture farms and allowing Greece's fishing fleet to grow again. Aquaculture, or fish farming, could help increase the supply of fish while also creating jobs for people who have lost work in traditional fishing. However, this solution may not help everyone, as some people may still struggle to find stable jobs. Local solutions have also been tried, such as community-led cleanups of abandoned fish farms. These efforts help restore coastal and marine ecosystems, which is important for long-term sustainability. Another idea is to use

seasonal fishing rules, which allow fish populations time to recover. This approach can help prevent overfishing and protect the environment. Neighboring countries have tried similar strategies by limiting fishing to certain seasons. While this may not be a perfect long-term solution, it could help stabilize the fishing industry while better plans are developed.

I would recommend reducing the number of large-scale fishing companies and giving more opportunities to local fishermen. This would help create more jobs and support smaller, local businesses. It could also reduce overfishing, since smaller operations usually fish in more sustainable ways. However, there are some challenges with this solution. Local fishermen may not be able to catch as much fish as large companies, which could temporarily lower the overall supply. Therefore this could lead to a small economic decline for Greece for a little while. Fishing is also a big part of Greek culture and daily life, so any changes could affect traditions and the local economy. The government would need to create policies to limit large fishing companies and support local fishermen. For large scale companies the fish caught and sold by smaller companies could be taxed and that money could contribute to paying the large fishing companies for leaving. This could include offering financial support or incentives to help smaller operations grow. One idea could be to limit how many boats one company can operate, such as allowing only a few boats per owner to reduce overfishing. That could leave for more opportunities for smaller fishing operations to take over.

Overall, this solution could be sustainable in the long run because it protects fish populations while also creating more local jobs. More local jobs could help increase the tourist industry and balance out the decrease in exportation of less fish. By also increasing local jobs it strengthens the economy and helps tackle coastal poverty. By focusing on smaller, community-based fishing and protecting the environment, Greece can work toward a stronger and more balanced fishing industry in the future.
